**SITUATION**

Around the world there are many remote communities not connected to a large, stable electrical grid. Canada, for example, has approximately 300 of these remote communities<sup>1</sup> and it is estimated there are up to 4,000 such communities globally. Typically, these small, isolated sites having unstable grid connectivity generate much or all of their electricity using diesel generators.

While diesel generators may have a relatively favourable capital cost, they have exceptionally high operating costs due to their low efficiency, combined with the high cost of transporting diesel fuel to remote sites, often under very difficult circumstances. Diesel fuel prices are expected to increase further in the coming years. In addition, diesel generators have extremely poor efficiency as they turn down in power. As a result, remote communities typically employ multiple diesel generators to meet their average and peak power demands.

Moreover, diesel generators create greenhouse gas (GHG) emissions that are harmful to local residents and the environment. Many remote communities are interested in improving utility service to support social well-being while, at the same time, reducing their dependence on diesel-powered electricity for social and environmental reasons. In addition, many governments are looking at ways to create job opportunities in these remote communities, leveraging alternative energy for job creation.

**SOLUTION**

Renewable sources of electricity, such as wind, hydropower and solar are particularly attractive for remote communities since they offer a clean source of power in locations that cannot be economically served by means of a grid extension.

While renewable power systems typically have relatively high capital cost, their operating costs are very low in comparison to diesel generators. Therefore, they have lower life-cycle cost and associated levelized cost of energy. Short term payback periods for renewable power systems relative to diesel systems are achievable, when combined with fuel cells.

**Figure 1: Renewable power system for a remote community.**

Significant issues with renewable power systems are their intermittency (or low capacity factor) and unpredictability. These systems cannot be relied upon to meet 100% of the power demand – there will be times when available renewable power is less than power demand.

These issues of intermittency and reliability can be effectively addressed by storing surplus off-peak power for use during peak power periods. Off-peak energy can be stored in the form of hydrogen (produced using renewable energy and electrolyzers), which will produce power during peak times by means of a fuel cell system. This allows the renewable power system to meet a very high percentage of power demand.

The photograph below shows a renewable power system installed in Bella Coola, a remote community in Northern British Columbia, Canada. The main source of power for this community is a run-of-river generator, whereby the natural flow and elevation drop of a local river are used to generate electricity. The surplus energy from the run-of-river generator is stored in a flow battery and is also used to produce hydrogen from water by means of electrolysis. To combat intermittency issues during periods of high water demand, the stored hydrogen is fed into a fuel cell system to generate electricity for the community.

Figure 2: Renewable power system at Bella Coola, British Columbia, Canada.

Fuel cells are capable of high power turn down and have higher efficiency at all power levels than conventional technologies, such as diesel generators. The fuel cells themselves release zero harmful emissions from their operation. Further efficiencies and reductions in GHG emissions can be realized when the waste heat from a fuel cell system is utilized for district heating.

## CASE STUDY

A techno-economic analysis was performed comparing a renewable wind-hydrogen power system to conventional diesel generators for a hypothetical remote community. Assumptions include: 30 year study period; 7.5% annual real interest rate; 162 kW annual average power demand; 392 kW peak power demand; \$2/L diesel fuel cost; 8 m/s wind speed.<sup>2</sup>

Figure 3: Wind-hydrogen vs. diesel generator-only power systems for a hypothetical remote community (All currencies in US funds)

While the wind-hydrogen system requires 3.2x more capital dollars, the levelized cost of energy for this renewable system is 38% lower than for the diesel generator (ie. \$0.671/kWh vs. \$1.076/kWh). With an annual operating cost savings of over \$900,000, a five-year payback is achieved for the renewable system.<sup>3</sup> In addition, the renewable system reduces CO2 emissions by 82%, removing almost 1,200 tonnes (US) of CO2 from the atmosphere annually.

## CONCLUSIONS

Energy storage in the form of hydrogen (using renewable sources and electrolyser technology) combined with power production using a fuel cell system can enable remote communities to meet all – or a significant proportion – of their power needs in a highly economical manner.

The adoption of renewable energy production and fuel cells provides a number of meaningful benefits for remote communities, including:

- improved air quality and reduced GHG emissions;
- economic development, including creation and retention of high-value jobs needed to plan, commission and manage renewable and fuel cell power installations; and
- movement toward energy independence and economic self-sufficiency.
